BOBCAT SURVEY - 1982-83

by

Thomas M. Cooley, Stephen M. Schmitt, and Paul D. Friedrich

Introduction

Pressure by concerned organizations and the Convention on International Trade in Endangered Species (CITES) has caused the Fish and Wildlife Service to compile comprehensive data on some furbearers. This documentation is necessary to verify the stability of populations and to justify continued harvesting and exportation of pelts.

During the winter of 1982-83, the Wildlife Division collected bobcats (*Felis rufus*) from hunters and trappers to increase the knowledge of this species, and to evaluate possible field techniques for sex and age determination.

Skinned bobcat carcasses were obtained from hunters and trappers throughout Michigan, and the following determinations made: sex, age, weight, dental measurements, physical condition, stomach contents, parasites present and reproductive history. This information was summarized for each region.

Materials and Methods

Each skinned bobcat carcass was weighed, sex determined, and various dental measurements taken (Appendix I). A complete necropsy examination was performed with each organ system being examined and any abnormalities recorded. A lower canine was used to estimate age by cementum layer counts following the method of Crowe (1975). Physical condition estimates were made by examining kidney fat (Riney 1955).

Reproductive history was established by ovarian inspection and by classification of corpora lutea (C.L.) condition (Crowe 1975). Ovaries were preserved in Mossman's AFA Fixative and the total number of C.L. determined by thin sectioning (1-3 mm) the ovaries. The remaining female reproductive tract was frozen for future examination of placental scars.

Adult parasites found during examination of the carcass were identified and some were preserved in 10% formalin for future identification. A 2-4 gm fecal sample was preserved in 10% formalin, and later examined by the sugar flotation method for identification of parasites (eggs and larvae). Stomach contents were examined and identified.

Results and Discussion

There appeared to be a correlation between sex and weight of bobcats in both regions, with males weighing more than females of the same age (Tables 3 and 9). There was, however, an overlap in the weights between age classes. The dental measurements (Tables 4 and 10) also showed this correlation.

Region I

The sex ratio of the bobcats examined from Region I (Table 1) was 100:82 (33:27), males to females. This ratio of slightly greater numbers of males to females agreed with the findings of Erickson (1955), Hoppe (1980), and Cooley et al. (1981, 1982). The percentage of young-of-the-year submitted was down for the second year in a row, falling from 40% in 1980-81, to 35% in 1981-82, and to 30% in 1982-83. The age groups 0 to 3 years for the third year in a row made up nearly 80% of the total animals submitted. The young-of-the-year and yearling age classes occurred most frequently in the sample.

Although the sample size was small, the C.L. counts (Table 2) were in general agreement with figures from the previous 2 years. Nearly 40% (4 of 11) of the 1-2 year age class animals exhibited evidence of having cycled twice in one breeding season. This was the third consecutive year that this phenomena has been seen in the Region I bobcats.

The kidney fat index (Table 5) was higher in all but one of the 0 to 4 year age and sex classes during the 1982-83 sampling. The mild winter probably was responsible for this difference. Only 4 (6.67%) of the bobcats examined were free of parasites (Table 6). Nearly three quarters of the bobcats had tapeworms of the genera Taenia and Spirometra and over 50% had ascarids of the genus Toxocara. The prevalence of the tapeworms was nearly the same as last year, but considerably higher than in the 1980-81 collection. The ascarid figures were markedly reduced from last year (79%), but close to the 1980-81 figures (46%). Five other genera of parasites were identified in the bobcats this year.

Region II

The sex ratio of bobcats examined from Region II (Table 7) was moderately skewed toward males: 100:65 (20:13). This was fairly consistent with the previously mentioned studies, but was considerably less than last year's ratio 100:35 (20 males:7 females). Only 18% of the animals were young-of-the-year, with age groups 1 to 6 years being nearly equally represented in the sample (9-15%).

The small number of female carcasses submitted precluded extensive analysis of C.L. counts (Table 8). It did appear that there were adequate numbers of C.L. to represent 3-5 C.L./ovulation (per year). There was a single yearling female that had 8 C.L. present, indicative of a heat period recycling.

The kidney-fat index (Table 11) was moderately to slightly lower than last year. Most of the values were within 15% of last year's figures.

Over 30% of the bobcats from Region II were free of parasites (Table 12). This was the highest percentage of parasite-free cats seen during the 3-year sampling period (19% in 1980-81 and 11% in 1981-82). Tapeworms (Spirometra sp. and Taenia sp.) were the most prevalent parasites seen (42%), while ascarids (Toxocara sp.) were in 39% of the cats, nearly half as prevalent as last year (74%).

Four other genera of parasites were identified in the bobcats this year.

Management Application

The collection and examination of bobcat carcasses provided additional baseline information. The development of new sexing techniques using dental measurements may allow for easier data collection in the future. This data, in conjunction with future information, will allow the Wildlife Division to develop a management model and hopefully assure Michigan trappers and hunters the opportunity to harvest and export this furbearing species in the future.

Acknowledgements

We thank the bobcat trappers and hunters for their voluntary cooperation and the biologists and technicians for gathering the bobcat carcasses and submitting them for examination. Thanks is also extended to Jan Miller who assisted in the preparation of this report.
