Wildlife Division Report No. 3120
March 1990

DEER CHECKING STATION DATA - 1989*

BY

Harry R. Hill and Dale L. Rabe

INTRODUCTION

The Wildlife Division has been collecting and tabulating measurements from hunter killed deer (*Odocoileus virginianus*) for the last 29 years, including data on antler beam diameters and the number of antler points in yearling bucks. These measurements are believed to reflect, in part, the physical condition of the deer herd. This report contains summaries of the deer physical data collected during 1989 and is intended to encourage comparison with similar data from past years.

Some of the data presented in this report were collected at three roadside check stations set up along major north-south highways across the state. A large number of deer were also checked at field stations throughout the state. Records on approximately 30,000 deer were submitted. However, some of the records contained incomplete or inaccurate information, so analyses were conducted on 29,000 records.

These data are not the result of a random sampling procedure, making statistical comparisons invalid, but these summaries still contain valuable information for use by wildlife managers. The fact that these data are collected from deer voluntarily brought to the check stations probably means that larger and/or older animals are more likely to be examined (Burgoyne 1981). It is assumed that these data have a similar bias in most years making it possible to use the data for comparing years and evaluating trends.

BEAM DIAMETERS AND ANTLER POINTS

RATIONALE

Antler size of yearling bucks are thought to indicate the relative physical condition of the herd. Growing antlers require considerable energy besides that necessary to keep the animal alive. Thus, a measurement of antler size should give some indication of the energy available to the animal; thus a poorly fed buck would be expected to have less antler development. However, antler development is also affected by both the absolute and the relative quantities of various nutrients in the food consumed.

For year-to-year comparisons, yearling bucks should provide the best information because (1) there are many of them harvested and examined, and (2) they have the added burden of completing their body growth while sprouting their first antlers.

*A contribution of Federal Aid in Wildlife Restoration, Michigan Project W-124-R.

Beam diameters are recorded as the average of two measurements on each antler 25 millimeters above the burr. In addition, the total number of antler points is recorded. Body weights might provide a more reliable index of physical condition but are not available in sufficient numbers for most areas. Beam diameters seem to provide a more sensitive measure of physical condition than does the number of antler points. All three are influenced in varying degrees by food conditions and other factors throughout the year. The variation in antler size between some years may be due, in part, to the presence of many bucks with unbranched antlers (spike horns) which are less vulnerable to hunters who do not have hunter's choice permits.

SEX AND AGE DATA

The last tables in this report contain sex and age-class data for the deer examined during the 1989 season. From these data it is possible to estimate the sex and age-class proportions in the population. Several factors determine how the age-class proportions in the harvest compare with the true age class proportions in the deer herd. The first is that hunters may try to select the largest deer. In doing so they may be selecting the older animals. Secondly, some age classes may be more vulnerable to hunting than others. In addition, hunters who take small deer or female deer may be less likely to bring them to a check station to be examined. The result of these factors may cause harvest estimates to be somewhat biased relative to the true sex and age structure of the population.
